#### ABSTRACT

**Background:** Observational studies have linked low vitamin D (VD) levels to increased asthma attacks in children. Subsequent meta-analyses of adults and children revealed that VD treatment might benefit asthmatic patients by reducing the incidence of exacerbations. Therefore, this review aims to analyze the effects of VD supplementation in reducing asthma exacerbations in children.

**Methods:** Published reports from PubMed, Cochrane, and Google Scholar were systematically searched until April 2023. The study protocol was registered in the PROSPERO database CRD42023411796. Randomized controlled trial studies were included in this review. Meta-analysis was performed using Cochrane RevMan 5.1 and presented with 95% confidence intervals (CIs). **Results:** Ten relevant studies enrolled 1243 asthmatic children (631 children receiving vitamin D3 supplementation, 612 children receiving placebo) were included in this review. Our pooled analysis found that VD supplementation had a significant effect on lowering the total number of asthma exacerbations (RR 0.62; 95% CI: 0.44, 0.87; p=0.01). Subgroup analysis revealed that a daily dose of VD given based on standard daily dose recommendation had a significant improvement on asthma exacerbations (IRR 0.41; 95% CI: 0,18, 0,92; p=0.03).

**Conclusions:** Vitamin D supplementation can lower the occurrence of exacerbations in children with asthma, along with the improvement of FEV1.

#### Introduction

Childhood asthma is the most common chronic condition that affects more than 6 million children in the US [1,2] and is one of the common causes of death in children [3]. More than half of asthmatic children experience minimum one acute attack a year, making it one of the main factors leading to school absenteeism and hospitalization in childhood [4]. Asthma exacerbations is multifactorial, recent observational studies have linked low vitamin D (VD) level to increased risk of asthma exacerbations [5]. VD deficiency was found in 74% of patients with asthma and in 54.5% of healthy children [6]. Low VD levels correlated with increased airway hyper-reactivity, reduced lung function, and reduced response to corticosteroid, thus increase asthma attacks

and severity in children [5,6]. These findings could be attributed VD's immune-modulating to and anti-inflammatory properties, which include the induction of regulatory T-cells, suppression of Th2 and Th17 responses, stimulation of IL-10 production, and inhibition of airway smooth muscle hypertrophy and collagen deposition [7-9]. VD also may reduce asthma attacks caused on by viral infections by inhibiting rhinovirus replication in bronchial epithelium, enhancing interferon-mediated antiviral pathways, and increasing production of antimicrobial peptides [10]. Subsequent meta-analyses of adults and children revealed that VD treatment might benefit asthmatic patients by reducing the incidence of exacerbations [1, 11]. Therefore, this review aims to analyze the effects of VD supplementation in reducing asthma exacerbations in children.

#### **Methods**

#### Search strategies

This review was carried out in compliance with the Preferred Reporting Items for Systematic Examination and Meta-Analysis (PRISMA) guidelines. The study protocol was registered in the PROSPERO database CRD42023411796. We systematically search published reports from PubMed, Cochrane, and Google Scholar up to April 2023 using medical subject heading (MeSH) and free-text terms: [((((vitamin D) OR (25-hydroxyvitamin D)) OR (25(OH)D)) OR (cholecalciferol)) OR (vitamin D3)] AND [(asthma) OR (bronchial asthma)] AND [(((children) OR (child)) OR (pediatric)) OR (adolescence)]. Type of study included in this review was Randomized Controlled Trials (RCTs) with no language limitation.

#### Study selection

Two reviewers screened the records independently. Inclusion criteria were as follows: (1) population: children diagnosed with asthma aged 0-18 years old; (2) intervention: vitamin D supplementation, regardless of the drug names, doses, and administration routines, or as an adjunct to other forms of asthma treatment; (3) comparison: either placebo or control group; (4) outcomes: reported in rate of asthma exacerbations and predicted percentage of forced expiratory volume in first second (FEV1%); (5) study design: randomized controlled trials (RCTs).

#### **Data extraction**

Data were extracted by two investigators (KF and LNR) independently to a collection form that had been made before. Data collected from studies were: name of the first author, publication year, country of origin, number of participant in intervention and control groups, age range of subjects, dose of vitamin D given as intervention, cumulative dose of vitamin D given, and duration of supplementation. Outcome data extracted were: rate of asthma exacerbations, mean vitamin D levels, and FEV1%. Meta-analysis was performed using Cochrane Revman 5.1 and presented with 95% confidence intervals (Cls).

#### Outcomes

The primary outcome was the rate of exacerbations. Asthma exacerbation was defined as an increased in symptoms (shortness of breath, cough, wheezing), a progressive decrease in pulmonary function, use of systematic corticosteroid (tablets, suspension, or injection) or increased use of short-acting  $\beta$ 2-agonists (SABA) bronchodilator [12]. This review analyzed subgroups of daily dose Vitamin D supplementation based on Vitamin D dosing basic principles that describe the recommended daily dose and upper tolerable daily dose of the patient based on their age. The intervention doses of included studies were classified into two groups: standard-dose and higher-dose, based on the age of subjects and the recommended daily dose [13]. The subgroups of duration of supplementation based on the median distribution. FEV1% and mean vitamin D levels were analyzed as different outcomes. FEV1% was calculated as a change from the baseline.

#### **Quality assessment**

Two reviewers (NLN and FFT) independently evaluated the quality of each selected study using the Joanne Briggs Institute (JBI) Critical Appraisal tools, checklist for Randomized Controlled Trials. If a discrepancy was found, senior researchers (RAS) were consulted.

#### **Statistical analysis**

Pooled outcomes analyses were assessed using forest plots and presented in 95% confidence intervals. Before identifying significant factors, data were assessed for heterogeneity and potential publication bias. The chi-square and l<sup>2</sup> tests were used to measure study heterogeneity; if p heterogeneity >0.05, and l<sup>2</sup> > 50%, a random-effects model was used. The rate of exacerbations was analyzed using an odd ratio, mean vitamin D level and FEV1% change was evaluated using pooled standardized mean difference (sMD). Data analysis used the Review Manager version 5.1 to analyze the data (Cochrane Collaboration, London, UK). Two authors (KF and QA) conducted statistical analyses independently to avoid methodological errors.

#### Results

#### Study selection

Using our search strategy, we observed 677 studies. There were 353 duplicate studies removed. Following a review of the titles and abstracts, 21 potentially relevant studies were identified. After reviewing the full-text, 11 studies were excluded because of the difference of the study design, the insufficient data provided and the different of cut off levels. Finally, we determined 10 studies that met our inclusion criteria. Figure 1 shows a flow chart depicting the study selection process.

This review included ten relevant studies that enrolled 1243 asthmatic children consisting of 631 children receiving vitamin D3 supplementation which then classified to the intervention group, and 612 children receiving placebo which then classified to the control group. The description of each study is shown in Table 1. The duration of supplementation ranges from 3 up to 12 months, with the daily dose given ranging from 150 IU/day up to 4000 IU/day. Eight studies analyzed the occurrence of asthma exacerbations in the intervention and the control group, six studies analyzed the mean vitamin D levels as measured by 25-hydroxyvitamin D in plasma, and four studies evaluated lung function as measured by FEV1.

#### **Study characteristics**

The characteristics of the included studies are described in Tables 1 and 2. 10 RCTs were blinded controlled, parallel-group trials that evaluated children and adolescents. Even two studies evaluated children from newborns and preschoolers [6, 14-22]. Included studies were from both developing and developed countries: three studies were conducted in India, two in Poland, and two in Japan, while the other three were conducted in US, Israel, and China. The extracted data about outcome measurements were as follows: the correlations between vitamin D and asthma exacerbations (8 studies), vitamin D levels after intervention (6 studies), and FEV1 (4 studies). The detailed characteristics of included studies were shown in Table 1. Furthermore, the 25(OH) D baseline differed between the studies, with three studies not providing a baseline. Five studies [6, 17, 20-22] enrolled only vitamin D-deficient (VDD) or vitamin D-insufficient participants. The other five did not identify vitamin D deficiency as an inclusion criterion, although many participants were VDD. The most commonly used category levels to characterize serum 25(OH)D deficiency, insufficiency, and sufficiency, respectivelv, were 20 ng/ml (50 nmol/l), 20-29.9 na/ml (50-74.9 nmol/l), and 30 ng/ml (75 nmol/l). All included studies were critically appraised using Joanne Briggs

Institute (JBI) Critical Appraisal tools, checklist for Randomized Controlled Trials. Three studies did not clearly report the reasons for subject's discontinuation or dropout [6, 15, 17]. One study did not treat the control and intervention group equally, as the control group only received inhaled budesonide, while the intervention group received inhaled budesonide+salbutamol and VD supplementation [19]. The risk of bias assessment of included studies was shown in Figure 2.

#### **Primary outcome**

## Effect of vitamin D supplementation on asthma exacerbations

Four out of eight trials included in our meta-analysis reported that VD supplementation had a significant effect on lowering the total number of asthma exacerbations [18, 20–22] (Figure 3). The cumulative pooled analysis showed a significant effect in the reduction of

Figure 2. Risk of bias assessment for included studies.

asthma exacerbations in VD supplementation group (RR 0.62; 95% CI: 0.44, 0.87; p=0.006) (Figure 4). Five out of eight studies included had a standard daily dose of VD given and showed a statistically significant improvement in asthma exacerbations (RR 0.55; 95% CI: 0,34, 0,89; p=0.01) (Figure 5). VD supplementation for <6 months can decrease the occurrence of asthma exacerbations, as seen in Figure 5 (RR 0.51; 95% CI: 0,33, 0,80; p=0.003) (Figure 6). VD supplementation with steroid treatment can lower the occurrence of asthma exacerbations compared to children with no steroid treatment (RR 0.54; 95% CI: 0,35, 0,84; p=0.0025) (Figure 7).

#### Secondary outcomes

Our study found a significant increase in VD levels in children with VD supplementation (SMD: 1.95; 95% CI: 1,32,2.57  $p=1\times10^{-4}$ ) (Figure 8). Out of 5 studies included with a VDD or VD insufficient levels participants, 3 of them [6, 21,22] shows an increase in VD levels and with a sufficient VD levels (Figure 8). There was also a significant improvement in predicted percentage of FEV1 levels in children with VD supplementation compared to the placebo group (SMD: -0.23 95% CI: -0,46, -0,01 p=0.04) (Figure 9). FEV1% was calculated as a change from the baseline.

Figure 3. Funnel plot of included studies.

#### Discussion

Our meta-analysis showed that asthma exacerbations were significantly lower in the intervention group compared to the placebo group. This finding is similar to a previous meta-analysis in adults which demonstrated a statistically significant reduction in asthma exacerbations in adults with low VD levels given VD supplementation. However, the aggregated estimate was insignificant among adolescents under 16 [11]. Our findings are also consistent with meta-analysis studies in general asthma populations, which suggest that vitamin D supplementation lowers the asthma exacerbations rate treated with

Figure 8. The effect of vitamin D supplementation on vitamin D levels.

systemic corticosteroids, particularly in individuals with vitamin D insufficiency [23,24]. According to the most recent research, vitamin D has significant immunomodulatory effects that inhibit airway inflammation, improve airway hyper-responsiveness, decrease gland secretion, slow bronchial smooth muscle cell growth, improve airway remodeling, boost the body's response to corticosteroids and decrease viral-induced asthma attack [21, 25–27]. Most exacerbations are caused by viral upper respiratory tract infections (URTIs), especially in young

children [6]. Vitamin D may attenuate viral-induced asthma attacks by reducing rhinovirus replication in bronchial epithelium, promoting interferon-mediated antiviral pathways and inducing the production of antimicrobial peptides [21].

Several studies have shown the effectiveness of vitamin D supplementation in reducing the incidence of exacerbations in asthma patients [1, 28]. However, none have analyzed the optimal dose and duration of supplementation in children. This review analyzed

subgroups for daily dose based on Vitamin D dosing basic principles [13]. The results of this review revealed that a daily dose of vitamin D in a standard recommended dose is more significant in decreasing exacerbations compared to those higher dose; the optimal duration was seen in subjects receiving supplementation <6 months. Previous clinical trials in patients with atopic dermatitis revealed that a weighted average dose of 1,500–1,600 IU per day for up to three months was associated with clinically significant benefits in reducing disease severity [29].

Standard recommended daily dose VD supplementation fits in with The Endocrine Society's vitamin D supplementation recommendations for children [30]. Higher dose of VD supplementation may not always give a better result because there is an optimal dose for VD supplementation in children. In a study involving the administration of 14,000 IU of vitamin D per week to children aged 13.5 3.6 years, there was no difference between the effects of vitamin D and placebo, even though vitamin D levels in the blood increased significantly [6]. Additionally, there are no specific recommendations regarding the duration of VD supplementation for respiratory health. The supplementation of adults with a high dose of vitamin D monthly for an average duration of 1.1 years, which increased serum 25(OH)D concentration by >50 nmol/L relative to placebo, did not enhance lung function in the study population [31]. One study found that infants with vitamin D deficiency who received ergocalciferol doses greater than 300,000 IU were at a high risk for hypercalcemia [32].

Our pooled analysis found that the mean vitamin D (25(OH)D) levels (four studies) were significantly higher in the intervention group than in the placebo group. This result was similar to the study that Vitamin D supplementation substantially altered serum vitamin D levels in asthmatic children [28]. Vitamin D supplementation may even diminish the lung function of patients [26]. The incidence of adverse events (AEs) was comparable between minors receiving vitamin D and those receiving placebos, so it was generally believed that vitamin D was safe [28].

This review revealed that even though vitamin D may decrease the occurrence of asthma exacerbations generally, the effect is more significant in subjects with steroid treatment compared to no steroid received. Vitamin D is thought to increase the expression of MAPK phosphatase 1 (MKP-1), another anti-inflammatory mechanism, which leads to corticosteroid-induced anti-inflammatory and immunosuppressive effects in peripheral blood mononuclear cells [33,34]. The method for reversing steroid resistance was enhanced

by adding vitamin D's ability to decrease fractalkine release [35]. Both corticosteroids and vitamin D are able to individually control the release of inflammatory chemokines in human airway smooth muscle; however, when both are administered together, an additive suppression of this chemokine is produced [36]. Vitamin D and corticosteroids have been shown to synergistically generate a tolerogenic dendritic cell (DC) phenotype that is crucial for immunomodulation and decreased reactivity to self and external antigens (such as allergens) [25]. Oral treatment of vitamin D (calcitriol) also reversed the effects of steroid resistance by activating IL-10-secreting Treqs [37,38]. The effects of VD supplementation were more significant in children than in adult with asthma [33]. It may be because airway remodeling is less common in children than in adults [33, 39,40].

This review also revealed a significant FEV1 improvement in subjects receiving vitamin D supplementation. This finding aligns with previous studies that found a positive correlation between vitamin D and lung function [24, 41]. A 6-week [6] and 15-week [42] Double-Blind Placebo-Controlled Trial study found no correlation between vitamin D supplementation and lung function. However, in an Iranian study conducted before, 8 and 24 weeks after vitamin D administration, FEV1 was significantly improved in the intervention group than the other group after 24 weeks [43]. The various immune modulatory characteristics of vitamin D in different cells were explained [44-46]; nevertheless, it takes time before vitamin D reaches the appropriate concentration and exhibits its effects. Vitamin D can improve lung function by attenuating Th2 and Th17 responses, enhancing IL-10 production, and inhibiting airway smooth muscle hypertrophy and collagen deposition [21].

A notable strength of our systematic review and meta-analysis is the inclusion of only randomized controlled trials (RCTs). RCTs are considered the gold standard in evidence-based medicine for assessing the efficacy of interventions, as they minimize the risk of various biases compared to other study designs. By exclusively including RCTs in our analysis, we have enhanced the internal validity of our findings and provided a robust basis for evaluating the impact of vitamin D supplementation on asthma exacerbations in children. One limitation of our systematic review and meta-analysis is the potential for publication bias. Despite our efforts to include all relevant studies, it is possible that some trials with null or negative results were not published or were difficult to access, leading to an overestimation of the beneficial effects of vitamin D supplementation on asthma exacerbations in children.

#### Conclusion

In conclusion, the available evidence suggests that vitamin D supplementation decreases the rate of asthma exacerbations in children and improves FEV1, but the effect is dose and duration related. A daily dose of vitamin D based on the standard daily dose recommendation is more significant in decreasing exacerbations compared to those receiving higher dose than the recommendation. The vitamin D supplementation effect was also seen as more significant in patients receiving steroid treatment compared to none. Overall, vitamin D supplementation may be a promising therapy for reducing asthma exacerbations rates in children.

#### **Author contributions**

KF and RAS designed the study. QA, LNR, NLN, FFT participated in data collection and literature search. LNR, NLN, FFT designed the keywords and screening all articles. KF, RAS, QA analyzed the results and drafted the manuscript. All authors have agreed to be accountable for all aspects of the work, ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved. All authors read and approved the final manuscript.
